

Figure 1: Markov chain 1

## 1 Sampling methods

Exercise 1.1 Forward Sampling. One strategy for obtaining an estimate of the conditional probability P(y|e) is by using forward sampling to estimate P(y,e) and P(e) separately, and then computing the ratio. We can use the Hoeffding Bound to obtain a bound on both the numerator and the denominator. Assuming that M is large, when does the resulting bound provide meaningful guarantees? Recall that we need  $M \leq \frac{\log(2/\delta)}{2\epsilon^2}$  to get an additive error bound  $\epsilon$  that holds with probability  $(1-\delta)$  for our estimate.

- a) It always provides meaningful guarantees.
- b) It never provides a meaningful guarantee.
- c) It provides a meaningful guarantee, but only when  $\delta$  is small relative to P(y, e) and P(e).
- d) It provides a meaningful guarantee, but only when  $\epsilon$  is small relative to P(y, e) and P(e).

**Exercise 1.2** Rejecting Samples. Consider the process of rejection sampling to generate samples from the posterior distribution P(Y|e). If we want to obtain M samples, what is the expected number of samples that would need to be drawn from P(X)?

a)  $M \cdot P(e)$ b)  $M \cdot P(Y|e)$ c)  $M \cdot (1 - P(Y|e))$ d)  $M \cdot (1 - P(Y|e))$ e) M/P(e)f) M/(1 - P(e))

**Exercise 1.3** Stationary Distributions. Consider the simple Markov chain of Figure 1. By definition, a stationary distribution  $\phi$  for this chain must satisfy which of the following properties? You may select 1 or more options, or none of them.

a)  $\phi(x_3) = 0.4\pi(x_1) + 0.5\phi(x_2)$ b)  $\phi(x_1) = 0.2\pi(x_1) + 0.3\phi(x_3)$ c)  $\phi(x_1) = 0.2\pi(x_1) + 0.4\phi(x_2) + 0.4\phi(x_3)$ d)  $\phi(x_1) = \pi(x_2) = \phi(x_3)$ e)  $\phi(x_1) + \pi(x_2) + \phi(x_3) = 1$ f)  $\phi(x_3) = 0.3\pi(x_1) + 0.7\phi(x_3)$ 

Exercise 1.4 Gibbs Sampling in a Bayesian Network. Suppose that we have the Bayesian network of Figure 2. If we are sampling the variable  $X_{23}$  as a substep of Gibbs sampling, which is the closed form for the distribution that we use to sample the value  $x_{23}^{'}$ ?

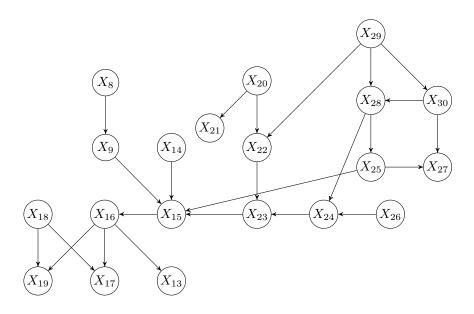

Figure 2: Large Bayesian network 1

- a)  $P(x'_{23}|x_{22},x_{24})$
- b)  $P(x'_{23}|x_{22},x_{24})P(x_{15}|x'_{23},x_{14},x_{9},x_{25})$

$$c) \ \left( P(x_{23}^{'}|x_{22},x_{24})P(x_{15}|x_{23}^{'},x_{14},x_{9},x_{25}) \right) / \left( \sum_{x_{22}^{''},x_{24}^{''},x_{15}^{''},x_{14}^{''},x_{9}^{''},x_{25}^{''}} P(x_{23}^{'}|x_{22}^{''},x_{24}^{''})P(x_{15}^{''}|x_{23}^{''},x_{14}^{''},x_{9}^{''},x_{25}^{''}) \right) + C \left( \sum_{x_{22}^{''},x_{24}^{''},x_{15}^{''},x_{14}^{''},x_{25}^{''}} P(x_{23}^{'}|x_{22}^{''},x_{24}^{''})P(x_{15}^{''}|x_{23}^{''},x_{14}^{''},x_{9}^{''},x_{25}^{''}) \right) + C \left( \sum_{x_{22}^{''},x_{24}^{''},x_{15}^{''},x_{14}^{''},x_{25}^{''}} P(x_{23}^{'}|x_{22}^{''},x_{24}^{''})P(x_{15}^{''}|x_{23}^{''},x_{14}^{''},x_{9}^{''},x_{25}^{''}) \right) + C \left( \sum_{x_{22}^{''},x_{24}^{''},x_{15}^{''},x_{14}^{''},x_{25}^{''}} P(x_{23}^{''}|x_{22}^{''},x_{24}^{''})P(x_{15}^{''}|x_{23}^{''},x_{14}^{''},x_{9}^{''},x_{25}^{''}) \right) + C \left( \sum_{x_{23}^{''},x_{24}^{''},x_{24}^{''},x_{25}^{''}} P(x_{23}^{''}|x_{22}^{''},x_{24}^{''})P(x_{15}^{''}|x_{23}^{''},x_{14}^{''},x_{9}^{''},x_{25}^{''}) \right) + C \left( \sum_{x_{23}^{''},x_{24}^{''},x_{25}^{''},x_{25}^{''},x_{25}^{''}} P(x_{23}^{''}|x_{25}^{''},x_{24}^{''})P(x_{15}^{''}|x_{25}^{''},x_{25}^{''},x_{25}^{''},x_{25}^{''}) \right) + C \left( \sum_{x_{23}^{''},x_{24}^{''},x_{25}^{''},x_{2$$

d)  $P(x_{23}^{'}|x_{-23})$  where  $x_{-23}$  is the tuple of values for all the rest of variables but  $X_{23}$ 

e) 
$$\left(P(x_{23}^{'}|x_{22},x_{24})P(x_{15}|x_{23}^{'},x_{14},x_{9},x_{25})\right)/\left(\sum_{x_{23}^{''}}P(x_{23}^{''}|x_{22},x_{24})P(x_{15}|x_{23}^{''},x_{14},x_{9},x_{25})\right)$$

f) None, as these are all either incorrect or not in closed form

**Exercise 1.5** Gibbs Sampling. Suppose we are running the Gibbs sampling algorithm on the chain Bayesian network  $X \to Y \to Z$ . If the current sample is  $(x_0, y_0, z_0)$  and we sample Y as the first substep of the Gibbs sampling process, which is the probability that the next sample is  $(x_0, y_1, z_0)$ ?

- a)  $P(x_0, y_1, z_0)$
- b)  $P(x_0, z_0|y_1)$
- c)  $P(y_1|x_0,z_0)$
- d)  $P(y_1|x_0)$

**Exercise 1.6** Collecting samples from Markov chains. Assume we run a Markov chain for a sufficient burn-in time, and now we wish to collect samples so that we can use them to estimate  $P(X_i = 1)$ . Can we collect and use every sample from the Markov chain after the burn-in?

- a) No, once we collect one sample, we have to continue running the chain in order to re-mix it before we get another sample.
- b) Yes, and if we collect m consecutive samples, we can use the Hoeffding bound to provide (high-probability) bounds on the error in our estimated probability.
- c) No, Markov chains are only good for one sample; we have to restart the chain and burn-in it before we can collect another sample.

d) Yes, that would give a correct estimate of the probability. However, we cannot apply the Hoeffding bound to estimate the error in our estimate.

Exercise 1.7 Markov Chain mixing. Which of the following classes of chains would you expect to have the shortest mixing time in general?

- a) Markov chains where state spaces are well connected and transitions between states have high probabilities.
- $b) \ \ \textit{Markov chains for networks with nearly deterministic potentials}.$
- c) Markov chains with many distinct and peaked probability modes.
- d) Markov chains with distinct regions in the state space that are connected by low probability transitions.
